Artificial Intelligence - INFOF311

Local search

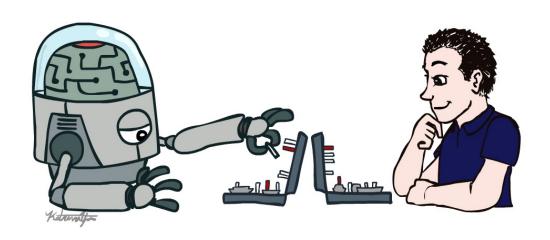

Instructor: Tom Lenaerts

Acknowledgement

We thank Stuart Russell for his generosity in allowing us to use the slide set of the UC Berkeley Course CS188, Introduction to Artificial Intelligence. These slides were created by Dan Klein, Pieter Abbeel and Anca Dragan for CS188 Intro to AI at UC Berkeley. All CS188 materials are available at http://ai.berkeley.edu.

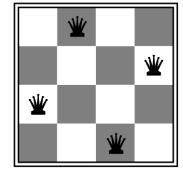

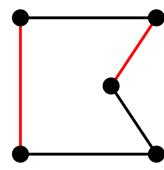

The slides for INFOF311 are slightly modified versions of the slides of the spring and summer CS188 sessions in 2021 and 2022

Local search algorithms

- In many optimization problems, path is irrelevant; the goal state is the solution
- Then state space = set of "complete" configurations; find configuration satisfying constraints, e.g., n-queens problem; or, find optimal configuration, e.g., travelling salesperson problem

- In such cases, can use iterative improvement algorithms: keep a single "current" state, try to improve it
- Constant space, suitable for online as well as offline search
- More or less unavoidable if the "state" is yourself (i.e., léarning)

Hill Climbing

Simple, general idea:

Start wherever

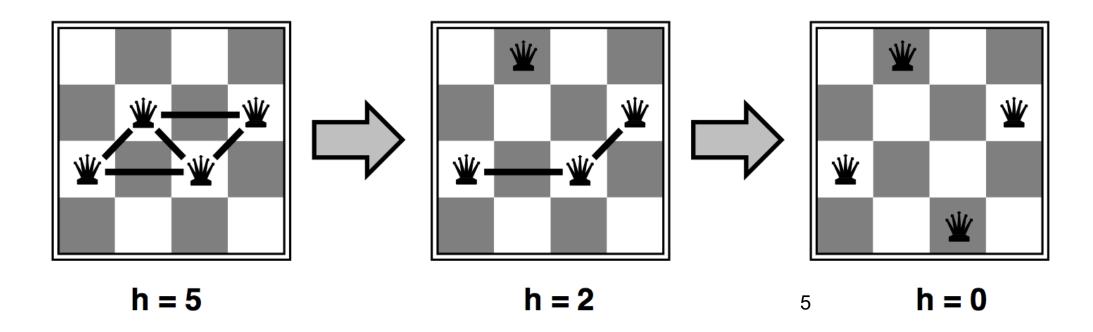

Repeat: move to the best neighboring state

If no neighbors better than current, quit

Heuristic for *n*-queens problem

- Goal: n queens on board with no conflicts, i.e., no queen attacking another
- States: n queens on board, one per column
- Actions: move a queen in its column
- Heuristic value function: number of conflicts

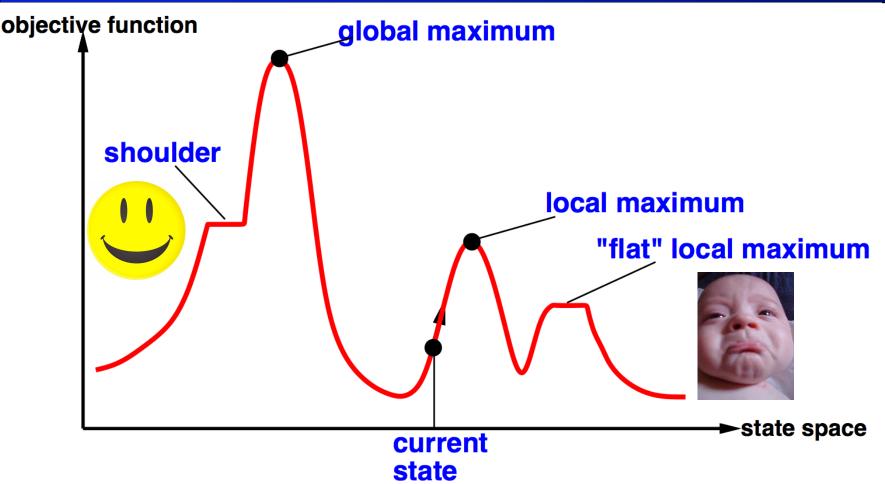

Hill-climbing algorithm

```
function HILL-CLIMBING(problem) returns a state
  current ← make-node(problem.initial-state)
  loop do
      neighbor ← a highest-valued successor of current
      if neighbor.value ≤ current.value then
           return current.state
      current ← neighbor
```

"Like climbing Everest in thick fog with amnesia"

Global and local maxima

Random restarts

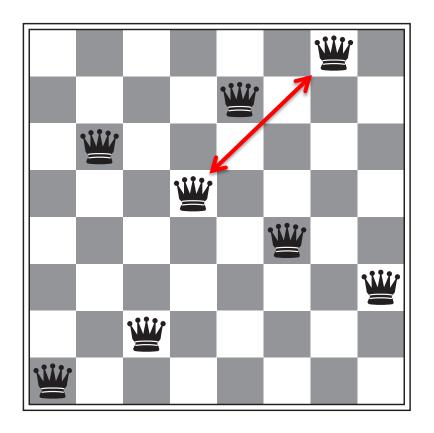

- find global optimum
- duh

Random sideways moves

- Escape from shoulders
- Loop forever on flat local maxima

Hill-climbing on the 8-queens problem

- No sideways moves:
 - Succeeds w/ prob. 0.14
 - Average number of moves per trial:
 - 4 when succeeding, 3 when getting stuck
 - Expected total number of moves needed:
 - 3(1-p)/p + 4 = 22 moves
- Allowing 100 sideways moves:
 - Succeeds w/ prob. 0.94
 - Average number of moves per trial:
 - 21 when succeeding, 65 when getting stuck
 - Expected total number of moves needed:
 - 65(1-p)/p + 21 =~ 25 moves

Moral: algorithms with knobs to twiddle are irritating

Simulated annealing

- Resembles the annealing process used to cool metals slowly to reach an ordered (low-energy) state
- Basic idea:
 - Allow "bad" moves occasionally, depending on "temperature"
 - High temperature => more bad moves allowed, shake the system out of its local minimum
 - Gradually reduce temperature according to some schedule
 - Sounds pretty flaky, doesn't it?

Simulated annealing algorithm

```
function SIMULATED-ANNEALING(problem, schedule) returns a state
current ← problem.initial-state
for t = 1 to \infty do
     T \leftarrow schedule(t)
     if T = 0 then return current
     next ← a randomly selected successor of current
     \Delta E \leftarrow next.value - current.value
     if \Delta E > 0 then current \leftarrow next
                else current \leftarrow next only with probability e^{\Delta E/T}
```

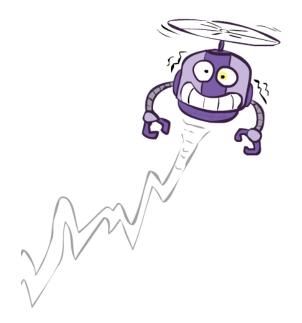

Simulated Annealing

Theoretical guarantee:

- Stationary distribution (Boltzmann): $P(x) \propto e^{E(x)/T}$
- If T decreased slowly enough, will converge to optimal state!

- The more downhill steps you need to escape a local optimum, the less likely you are to ever make them all in a row
- "Slowly enough" may mean exponentially slowly
- Random restart hillclimbing also converges to optimal state...
- Simulated annealing and its relatives are a key workhorse in many optimal configuration problems

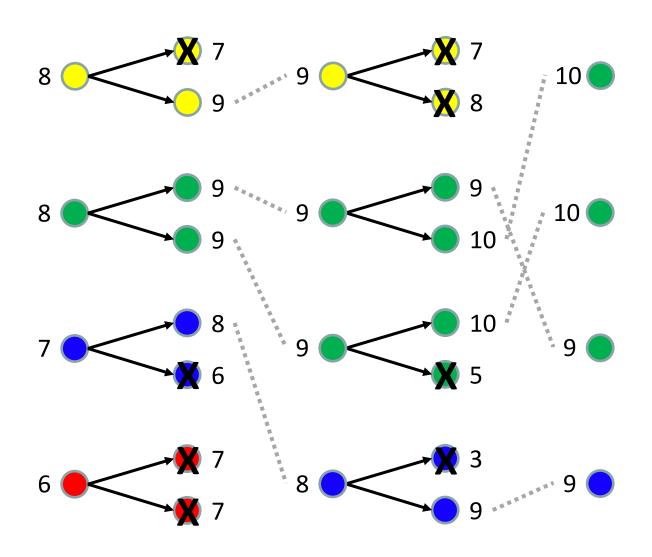

Local beam search

Basic idea:

- K copies of a local search algorithm, initialized randomly
- For each iteration
 Or, K chosen randomly with a bias towards good ones
 - Generate ALL successors from K current states
 - Choose best K of these to be the new current states

Beam search example (K=4)

Local beam search

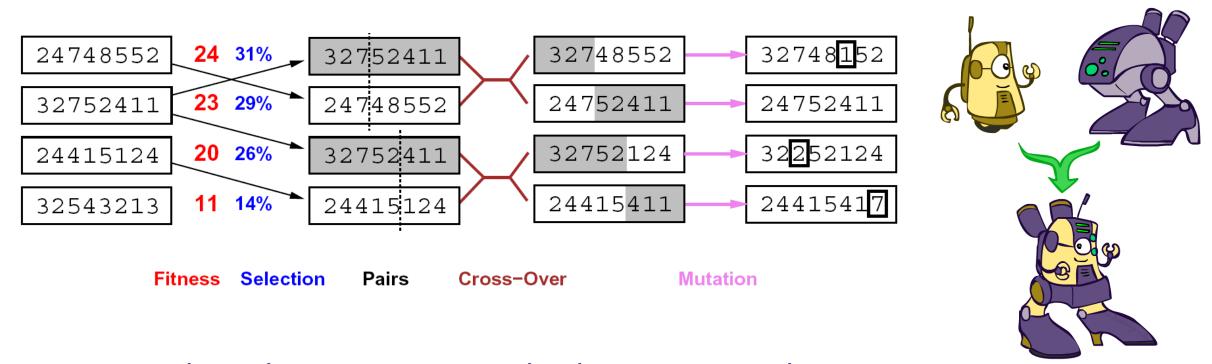

- Basic idea:
 - K copies of a local search algorithm, initialized randomly
 - For each iteration

Or, K chosen randomly with a bias towards good ones

- Generate ALL successors from K current states
- Choose best K of these to be the new current states
- Why is this different from K local searches in parallel?
 - The searches *communicate*! "Come over here, the grass is greener!"
- What other well-known algorithm does this remind you of?
 - Evolution!

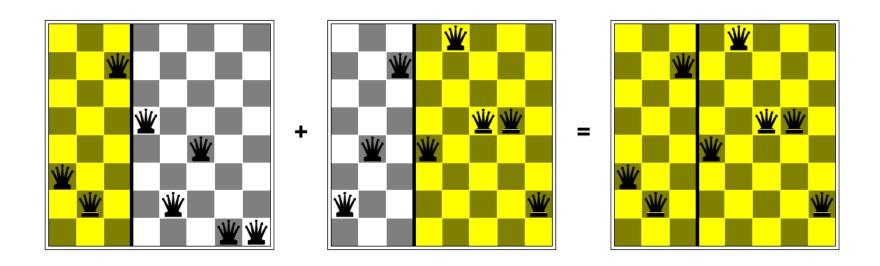

Genetic algorithms

- Genetic algorithms use a natural selection metaphor
 - Resample K individuals at each step (selection) weighted by fitness function
 - Combine by pairwise crossover operators, plus mutation to give variety

Example: N-Queens

- Does crossover make sense here?
- What would mutation be?
- What would a good fitness function be?

The algorithm

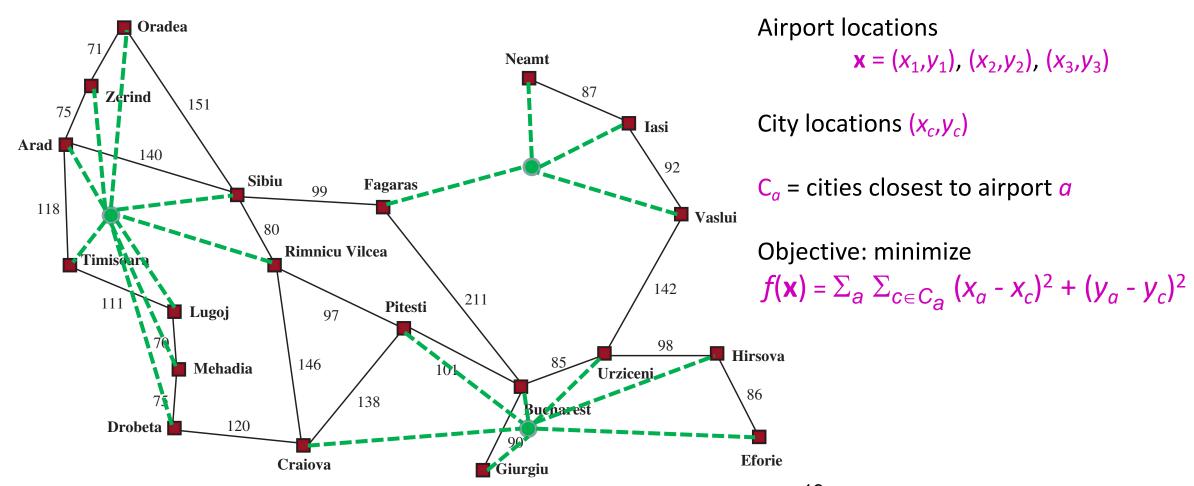

```
function GENETIC-ALGORITHM(population, fitness) returns an individual
  repeat
      weights \leftarrow WEIGHTED-BY(population, fitness)
      population2 \leftarrow empty list
      for i = 1 to SIZE(population) do
          parent1, parent2 \leftarrow WEIGHTED-RANDOM-CHOICES(population, weights, 2)
          child \leftarrow REPRODUCE(parent1, parent2)
          if (small random probability) then child \leftarrow MUTATE(child)
          add child to population2
      population \leftarrow population2
  until some individual is fit enough, or enough time has elapsed
  return the best individual in population, according to fitness
function REPRODUCE(parent1, parent2) returns an individual
  n \leftarrow \text{LENGTH}(parent1)
  c \leftarrow random number from 1 to n
  return APPEND(SUBSTRING(parent1, 1, c), SUBSTRING(parent2, c + 1, n))
```

Local search in continuous spaces

Example: Siting airports in Romania

Place 3 airports to minimize the sum of squared distances from each city to its nearest airport

Handling a continuous state/action space

1. Discretize it!

- Define a grid with increment δ , use any of the discrete algorithms
- 2. Choose random perturbations to the state
 - a. First-choice hill-climbing: keep trying until something improves the state
 - b. Simulated annealing
- 3. Compute gradient of f(x) analytically

Summary

- Many configuration and optimization problems can be formulated as local search
- General families of algorithms:
 - Hill-climbing, continuous optimization
 - Simulated annealing (and other stochastic methods)
 - Local beam search: multiple interaction searches
 - Genetic algorithms: break and recombine states

Many machine learning algorithms are local searches
